

Foundations of Cybersecurity

Module 1

Welcome to the exciting world of cybersecurity

Module 2

The evolution of cybersecurity

Module 3

Protect against threats, risks, and vulnerabilities

Module 4

Cybersecurity tools and programming languages

Important cybersecurity tools

Welcome to module 4

Course cybersecurity tools

Task for protecting business operations

Explore Tools and their purposes

Test your knowledge: Important cybersecurity tools

Core cybersecurity knowledge and skills

Introduction to Linux, SQL, and Python

Use tools to protect business operations

Test your knowledge: Core cybersecurity knowledge and skills

Create a cybersecurity portfolio

Portfolio Activity: Draft a professional statement

Portfolio Activity: Elevator Pitch a professional statement

Review Cybersecurity tools and programming languages

Coach Kitigan: Explore entry-level security analyst responsibilities

Settings

Previously, you were introduced to programming, operating systems, and tools commonly used by cybersecurity professionals. In this reading, you'll learn more about programming and operating systems, as well as other tools that entry-level analysts use to help protect organizations and the people they serve.

Tools and their purposes

Programming

Programming is a process that can be used to create a specific set of instructions for a computer to execute tasks. Security analysts use programming languages, such as Python, to execute automation. Automation is the use of technology to reduce human and manual effort in performing common and repetitive tasks. Automation also helps reduce the risk of human error.

Another programming language used by analysts is called Structured Query Language (SQL). SQL is used to create, interact with, and request information from a database. A database is an organized collection of information or data. There can be millions of data points in a database. A data point is a specific piece of information.

Operating systems

An operating system is the interface between computer hardware and the user. Linux®, macOS®, and Windows are operating systems. They each offer different functionality and user experiences.

Previously, you were introduced to Linux as an open-source operating system. Open source means that the code is available to the public and allows people to make contributions to improve the software. Linux is not a programming language; however, it does involve the use of a command line within the operating system. A command is an instruction telling the computer to do something. A command-line interface is a text-based user interface that uses commands to interact with the computer. You will learn more about Linux, including the Linux kernel and GNU, in a later course.

Web vulnerability

A web vulnerability is a unique flaw in a web application that a threat actor could exploit by using malicious code or behavior, to allow unauthorized access, data theft, and malware deployment.

To stay up-to-date on the most critical risks to web applications, review the Open Web Application Security Project (OWASP) Top 10.

Antivirus software

Antivirus software is a software program used to prevent, detect, and eliminate malware and viruses. It is also called anti-malware. Depending on the type of antivirus software, it can scan the memory of a device to find patterns that indicate the presence of malware.

Intrusion detection system

An intrusion detection system (IDS) is an application that monitors system activity and alerts on possible intrusions. The system scans and analyzes network packets, which carry small amounts of data through a network. The small amount of data makes the detection process easier for an IDS to identify potential threats to sensitive data. Other occurrences an IDS might detect can include theft and unauthorized access.

Encryption

Encryption makes data unreadable and difficult to decode for an unauthorized user. Its main goal is to ensure confidentiality of private data. Encryption is the process of converting data from a readable format to a cryptographically encoded format. Cryptographic encoding means converting plaintext into secure ciphertext. Plaintext is unencrypted information and secure ciphertext is the result of encryption.

Note: Encoding and encryption serve different purposes. Encoding uses a public conversion algorithm to enable systems that use different data representations to share information.

Penetration testing

Penetration testing, also called pen testing, is the act of participating in a simulated attack that helps identify vulnerabilities in systems, networks, websites, applications, and processes. It is a thorough risk assessment that can evaluate and identify external and internal threats as well as weaknesses.

Key takeaways

In this reading, you learned more about programming and operating systems. You were also introduced to several new tools and processes. Every organization selects their own set of tools. Therefore, the more tools you know, the more valuable you are to an organization. Tools help security analysts complete their tasks more efficiently and effectively.

coach

Hi, Venkatesh!

How can I help?

Explain this topic in simple terms

Give me a summary

Give me practice questions

Give me real-life examples

Ask me anything
