☒ True

False

✔ **Correct**

That's correct! A watermark is a heuristic, representing the point in event time where the system believes all data has arrived. While it's a strong signal, DeltaLake's architecture allows for "late data" to arrive after the watermark has passed. You can configure how to handle this late data.

1 / 1 point

☐ Correctly indexing player events that arrive from different geographic regions with different network speeds.

✔ **Correct**
That's correct! Dataflow uses event-time processing and watermarks to handle out-of-order data.

☒ Correct

- Generating the initial raw JSON data from the game clients.

- Ensuring data is not lost or processed twice if a worker node unexpectedly fails

✔ **Correct**
That's correct! Dataflow ensures fault tolerance and exactly-once processing semantics.

☐ Authenticating user identities on the fan engagement website.

1 / 1 point

☐ Flood (Tumbling) Windows of 2 minutes.

☐ Sliding (Hopping) Windows with a 2-minute duration and a 30-second period.

- Session Windows with a 2-minute gap duration.
- Global Windows with a time-based trigger.

- Global Wires with a time-based trigger

That's right! Session windows are specifically designed for this scenario. They group elements by key (in this case, `player_id`) and define a window that ends after a specified period of inactivity (the "gap duration"). This matches the requirement to identify when a player has gone idle or disconnected.
