Your latest: 100% • Your highest: 100% • To pass you need at least 80%. We keep your highest score.

Reveal Answer

1. What is the role of the permissions.json file in an MCP client?

1 / 1 point

- ☐ It describes the JSON schemas used for elicitation prompts.
- ☐ It enables servers to override client security settings when needed.
- ☒ It stores client-side policies that determine whether tools run automatically, require approval, or are blocked.
- ☐ It defines server-side authentication rules for user login.

Nice work

permissions.json enforces Allow, Ask, and Deny tool policies before any server communication.

2. How does elicitation differ from permissions in MCP?

2 / 1 point

- ☒ Permissions control whether a tool executes, while elicitation requests structured user input using JSON schemas when additional clarification or confirmation is needed.
- ☐ Permissions collect structured user input, while elicitation decides whether a tool runs.
- ☐ Elicitation enforces global tool policies stored in configuration files.
- ☐ Both permissions and elicitation are enforced only on the server.

Nice work

Permissions gate execution; elicitation validates and structures required user data.

3. Which scenario best demonstrates a high-risk MCP action that should require both approval and elicitation?

3 / 1 point

- ☐ Executing a one-time database query for reporting.
- ☒ Deleting a critical production resource when the client prompts for approval and then requests a justification using a JSON schema before proceeding.
- ☐ Updating UI text in a local configuration file.
- ☐ Listing files in a project directory.

Nice work

High-risk and destructive actions require explicit user approval and structured elicitation before execution.

4. How are permission policies, such as allow, deny, and ask, typically applied in an MCP security system?

4 / 1 point

- ☒ They are configured on the client to control whether tool execution runs automatically, requires approval, or is blocked entirely.
- ☐ They are defined and enforced only by the MCP server through tool metadata.
- ☐ They are embedded inside Python class inheritance structures.
- ☐ They are triggered only after a tool finishes executing.

Nice work

Client-side permission policies determine execution behavior before a tool is invoked.

5. What role does elicitation using JSON schemas play in an MCP security workflow?

5 / 1 point

- ☒ It requests structured user input when additional confirmation or data is required before performing an operation.
- ☐ It automatically assigns risk levels to tools.
- ☐ It replaces the need for permission policies such as allow, deny, and ask.
- ☐ It configures GUI-based permission controls in the client application.

Nice work

JSON schema-based elicitation ensures well-validated user input for sensitive or contextual actions.
