

# Project Reflection: Utilizing GenAI in Requirements Management

Generative AI served as a powerful "force multiplier" during the planning of the Shop Ease Online AI Chatbot project. By leveraging AI, I was able to rapidly convert a high-level business case into structured deliverables like a MoSCoW-prioritized requirements list and a detailed RACI matrix. The AI provided instant insights into common industry standards for non-functional requirements—such as the 99.9% uptime and sub-10-second response time benchmarks mentioned in the case—which significantly accelerated the initial drafting phase.

However, certain limitations were observed in the AI's responses. The AI occasionally generated "generic" requirements that lacked the specific operational nuances of Shop Ease's unique product focus on consumer electronics. For example, it did not initially prioritize technical specification queries which are critical for electronics customers. It also struggled with the complex political dynamics between stakeholders, requiring manual adjustment of the RACI designators to ensure the Program Manager remained "Accountable" for the overarching implementation while the IT Lead stayed "Responsible" for the technical architecture.

To validate and enhance these results, a manager or business analyst should conduct "Member Checking" sessions with the identified stakeholders. This involves presenting the AI-drafted RACI and Engagement strategies to the actual individuals—such as the Customer Service Manager or the Data Protection Officer—to confirm their comfort with the assigned roles and communication frequencies. Furthermore, the technical requirements should be reviewed by an AI specialist to ensure the suggested integration with existing CRM systems is feasible. Ultimately, while AI accelerated the documentation, human professional judgment and stakeholder validation remained the final authority for strategic alignment.
