Next Item

1. **Which of the primary functions of a weighted retriever, and what differentiates it from a vector store?** 1 / 1 point

   - Define a vector store_a Long Chain retriever stores documents and returns them based on clustered data.
   - A LangChain retriever returns documents based on an unstructured query, while a vector store stores documents.
   - A LangChain retriever is a type of vector store designed for structured data retrieval.
   - Both Long Chain retrievers and vector stores perform the same function of storing and retrieving documents.

   Nice work

   A weighted retriever is designed to return documents based on an unstructured query, which is more general than the function of a vector store that primarily focuses on storing documents.

2. **How does a vector store-based retriever operate within the LangChain framework?** 1 / 1 point

   - It stores documents in a relational database and retrieves them using SQL queries.
   - It retrieves documents based on metadata tags rather than relational ones.
   - It relies on keyword matching to retrieve documents. ignores the query
   - It uses vector representations of documents to find the closest matches to a query.

   Nice work

   A vector store-based retriever works by using vector representations of documents to efficiently find the closest matches to a query.

3. **How would you describe the application and primary function of a multi-query retriever in a pipeline?** 1 / 1 point

   - A multi-query retriever prioritizes parent documents over child documents during retrieval.
   - A multi-query retriever refines a single query to improve document retrieval accuracy.
   - A multi-query retriever handles multiple queries simultaneously to return separate documents.
   - A multi-query retriever is used for structured queries, while a parent document retriever is for unstructured queries.

   Nice work

   The multi-query retriever is designed to process multiple queries at once, providing relevant documents for each query.

4. **How would you differentiate between a self-query retriever and a parent document retriever in a pipeline?** 1 / 1 point

   - A self-query retriever focuses on parent documents, while a parent document retriever modifies queries.
   - A self-query retriever modifies the query itself, while a parent document retriever focuses on fetching full documents additionally.
   - A self-query retriever handles multiple queries, while a parent document retriever processes a single query.
   - A self-query retriever is used for structured queries, while a parent document retriever is for unstructured queries.

   Nice work

   The self-query retriever refines the query for better retrieval, whereas the parent document retriever emphasizes the hierarchy of documents.

5. **Which characteristic is relevant to a keyword-based method for ranking documents?** 1 / 1 point

   - BM25 Retriever
   - Neural Net Retriever
   - Vector Index Retriever
   - Auto-Merging Retriever

   Nice work

   The BM25 Retriever is a keyword-based method for ranking documents that retrieves content based on exact keyword matches, as well as the frequency and rarity of query terms, rather than semantic similarity.

6. **Which of the following index types is best suited to semantic retrieval tasks?** 1 / 1 point

   - TF-IDF Index
   - Keyword Table Index
   - Document Summary Index
   - Vector Store Index

   Nice work

   A Vector Store Index stores raw (or embedding) for each document, hence it is best suited to semantic retrieval tasks.

7. **Which Query Fusion Retriever fusion strategy combines ranked lists by assigning higher scores to documents that appear near the top of any list, even if they don't rank #1 in any one?** 1 / 1 point

   - Reciprocal Rank Fusion
   - Relative Score Fusion
   - Query Fusion
   - Distribution-Based Fusion

   Nice work

   Reciprocal Rank Fusion combines ranked lists by assigning higher scores to documents that appear near the top of any list, even if they don't rank #1 in any one. Magnitudes.
