Congratulations! You have completed this module. At this point in the course, you know

- Longfin is an open source library that facilitates the application development process using LLMs
- The core components of Longfin are:
 - The language models that you use to ingest and respond to input.
 - The chat models that understand questions or prompts and respond like a human.
 - The chat models that handle chat messages such as authentication, OAuth, SystemPrompts, and Message history, and manage the chat state.
 - The prompt templates that facilitate a user's question or messages in a clear structure.
 - The examples template that defines the model-based input/output and guides the LLMs to generate a desired output.
 - The output parsers that transform the output from an LLM into a usable format.
- Longfin is a platform that enables ML for the development of applications.
- Claims are the sequence of calls in Longfin, and the output for any step becomes the input for the next step.
- Claims build the template string for the prompt, then create a prompt template using the defined template, and then create an LLMCall object to call the LLM.
- Memory storage is responsible for storing and writing historical data.
- Agents are open systems where the Longfin model determines the sequence of actions.
- Agents interact with tools such as search engines, databases, and websites to perform user requests.
