1. **When you're developing a web application that needs to verify its responses against real-world data, why should you use a search-based grounding tool, rather than relying on the model's internal knowledge?** 1 / 1 point
   Select the best answer.
   - The grounding tool increases the processing speed of the application by allowing the model to skip the verification step.
   - **The grounding tool allows the model to supplement its existing knowledge with real-time web results and cite specific, current sources.**
   - The grounding tool enables the model to bypass the API key and directly access public web indices.
   - The grounding tool converts the response into a structured JSON schema without requiring a second model call.

   Nice work
   Correct! Grounding ensures that the API answers are based on fresh, external information. This reduces AI hallucinations and provides the user with verifiable sources for the information provided.

2. **In a notebook script where you've declared a function for a unit test case, why is it important to set additional properties in that within the parameters schema? Select the best answer.** 1 / 1 point
   - It requires the model to ignore the user's input and only generate random values.
   - **It helps the model fully understand the specific tool defined in the schema and prevents it from including unnecessary parameters.**
   - It allows the model to suggest new properties that are not currently in the allowed list.
   - It increases the runtime of the scripts allow the model more time to find the best options to respond to.

   Nice work
   Correct! By strictly defining the schema and preventing additional properties, you ensure that the model provides exactly what your function expects, reducing the risk of errors in your application logic.

3. **A developer you are working with is trying to better understand the project the two of you are developing. He says, "When we're developing intelligent systems, what effect would you expect to achieve if you set the temperature parameter to a very low value, such as 0.1, when calling the Gemini API?"** 1 / 1 point
   Select the best answer.
   - **The effect would be the ability to be trained into the real-time data from external sources, such as live traffic or library overdrive.**
   - The effect would be a deterministic list of a number of words the model is trained on to inform its choices.
   - The effect would be the speed at which the hardware GPU runs absolute float values, such as cloud distances.
   - The effect would be the model's capacity to generate creative letters like stories or poetry, without human intervention.

   Nice work
   Correct! Similar to a line navigation app, a dynamic AI interacts with a changing environment. It doesn't just rely on fixed, pre-loaded knowledge, it can search out to get the most current information available.

4. **In the context of retrieval and evaluation applications you are currently working on, you find that you need to store items in a JavaScript Object Notation (JSON) implementation in a dynamic AI agent. What is the most significant shift this change will make to the model's capability? Select the best answer.** 1 / 1 point
   - The model will use the knowledge to request more from external tools to perform tasks or access real-time data.
   - The model will increase its recall and overall vocabulary in authentic interfaces, including things like accents and literature.
   - The model will be retrained on more recent device make sure its internal knowledge remains current without external help.
   - **The model will start to ignore the user's latest prompt as its instructions priorities speed and reduce real-time access in an effort to store and update new information.**

   Nice work
   Correct! This is the key shift from a static model to a dynamic agent. By speeding it uses tools via function calling, the model can access tools to observe and interact with the outside world.

5. **Why might a systems architect choose a manufactured generation prompt over a more complex agentic workflow for a specific application? Select the best answer.** 1 / 1 point
   - To increase the reliability of the system by adding additional money (part) and more external tools
   - **To reduce the time it takes for the system to respond and to minimize the total cost of token usage**
   - To allow the assistant to access a proprietary database lookup tool without writing any Python code
   - To make sure the model can bypass human in the loop requirements for sensitive financial transactions

   Nice work
   Correct! Agentic workflows involve multiple "thinking" steps and back-and-forth communication with tools, which increases latency and token consumption. For simple tasks, a standard prompt is more efficient.
